

■ Joint distribution functions

For any two random variables X & Y , the joint cumulative probability distribution func. of X & Y by,

$$F(a, b) = P\{X \leq a, Y \leq b\} \quad -\infty < a, b < \infty.$$

The distribution of X can be obtained from the joint distr. of X & Y as follows:

$$F_X(a) = P(X \leq a)$$

$$= P(X \leq a, Y < \infty)$$

$$= P\left(\lim_{b \rightarrow \infty} (X \leq a, Y \leq b)\right)$$

$$= \lim_{b \rightarrow \infty} P(X \leq a, Y \leq b)$$

$$= \lim_{b \rightarrow \infty} F(a, b)$$

$$= F(a, \infty)$$

Similarly, $F_Y(b) = F(\infty, b)$

$$P(X > a, Y > b) = 1 - P(\{X > a, Y > b\}^c)$$

$$= 1 - P(\{X > a\}^c \cup \{Y > b\}^c)$$

$$= 1 - P(\{X \leq a\} \cup \{Y \leq b\})$$

$$= 1 - [P\{X \leq a\} + P\{Y \leq b\} - P\{X \leq a, Y \leq b\}]$$

$$= 1 - F_X(a) - F_Y(b) + F(a, b) \rightarrow \textcircled{1}$$

Eqn (1) is a special case of the following eqn.

$$P \{a_1 < X \leq a_2, b_1 < Y \leq b_2\}$$

$$= F(a_2, b_2) + F(a_1, b_1) - F(a_1, b_2) - F(a_2, b_1).$$

where, $a_1 < a_2, b_1 < b_2$

In the case when X & Y are both discrete random variables, it is convenient to define the joint probability mass functions of X & Y by:

$$p(x, y) = P \{X=x, Y=y\}$$

The prob. mass func. of X can be obtained from $p(x, y)$ by:

$$\begin{aligned} p_X(x) &= P \{X=x\} \\ &= \sum_y p(x, y) \end{aligned}$$

Similarly, $p_Y(y) = \sum_x p(x, y)$

Example:

Suppose that 15 percent of the families in a certain community have no children, 20 percent have 1 child, 35 percent have 2 children and 30 percent have 1. Suppose further that in each family each child is equally to be a boy or a girl. If a family is chosen at random from this community, then B , the number of boys and G , the number of girls in

this family will have the joint prob. mass func. shown in the table:

$$P\{B=i, G=j\}$$

$i \backslash j$	0	1	2	3	Row Sum
0	0.15	0.10	0.0875	0.0375	0.3750
1	0.10	0.175	0.1125	0	0.3875
2	0.0875	0.1125	0	0	0.2000
3	0.0375	0	0	0	0.0375
Col. Sum	0.3750	0.3875	0.2000	0.0375	

The probabilities shown in the above table are obtained as follows:

$$P\{B=0, G=0\} = P\{\text{No children}\} = 0.15$$

$$\begin{aligned} P\{B=0, G=1\} &= P\{1 \text{ girl \& total of 1 child}\} \quad (\text{not } 0.20) \\ &= P\{1 \text{ child}\} \cdot P\{1 \text{ girl} / 1 \text{ child}\} \\ &= 0.20 \times \frac{1}{2} \end{aligned}$$

$$\begin{aligned} P\{B=0, G=2\} &= P\{2 \text{ girls and total 2 children}\} \\ &= P\{2 \text{ children}\} \times P\{2 \text{ girls} / 2 \text{ children}\} \\ &= 0.35 \times \left(\frac{1}{2}\right)^2 \end{aligned}$$

We say that X & Y are joint continuous if \exists a func. $f(x, y)$ defined for all real (x, y) , having the prop. that for every set C of pairs of real numbers,

$$P\{(X, Y) \in C\} = \iint_{(x, y) \in C} f(x, y) dx dy$$

The func. $f(x,y)$ is called the joint prob. density func. of X & Y . If A & B are any sets of real numbers, then by defining $C = \{(x,y): x \in A, y \in B\}$ we see from eqn (2) that,

$$P\{X \in A, Y \in B\} = \iint_{B \times A} f(x,y) dx dy$$

$$\begin{aligned} \text{Now, } F(a,b) &= P\{X \in (-\infty, a], Y \in (-\infty, b]\} \\ &= \int_{-\infty}^b \int_{-\infty}^a f(x,y) dx dy \end{aligned}$$

it follows upon diff. that

$$f(a,b) = \frac{\partial^2}{\partial a \partial b} F(a,b)$$

If X & Y are jointly cont., they are individually cont. & their prob. distr. is given as:

$$\begin{aligned} P\{X \in A\} &= P\{X \in A, Y \in (-\infty, \infty)\} \\ &= \int_A \int_{-\infty}^{\infty} f(x,y) dy dx \\ &= \int_A f_X(x) dx \end{aligned}$$

where, $f_X(x) = \int_{-\infty}^{\infty} f(x,y) dy$ is the prob. density func. of X .

Similarly prob. density func. of Y is,

$$f_Y(y) = \int_{-\infty}^{\infty} f(x,y) dx$$

Example:

The joint density func. of X & Y is given by,

$$f(x,y) = \begin{cases} 2e^{-x} \cdot e^{-2y} & 0 < x < \infty, 0 < y < \infty \\ 0 & \text{otherwise} \end{cases}$$

Compute: (a) $P\{X > 1, Y < 1\}$

(b) $P\{X < Y\}$

(c) $P\{X < a\}$

$$\Rightarrow \text{(a) } P\{X > 1, Y < 1\} = \int_0^1 \int_1^{\infty} 2e^{-x} \cdot e^{-2y} dx dy$$

$$= \int_0^1 2e^{-2y} (e^{-x} \Big|_1^{\infty}) dy$$

$$= e^{-1} \int_0^1 2e^{-2y} dy$$

$$= e^{-1} (1 - e^{-2})$$

(b) $P\{X < Y\}$

$$= \iint_{(x,y): x < y} 2e^{-x} e^{-2y} dx dy$$

$$= \int_0^{\infty} \int_0^y 2e^{-x} \cdot e^{-2y} dx dy$$

$$= \int_0^{\infty} 2e^{-2y} (1 - e^{-y}) dy$$

$$= \int_0^{\infty} 2e^{-2y} dy - \int_0^{\infty} 2e^{-3y} dy$$

$$= 1 - \frac{2}{3} = \frac{1}{3}$$

$$\text{(c) } P\{X < a\} = \int_0^a \int_0^{\infty} 2e^{-2y} e^{-x} dy dx$$
$$= \int_0^a e^{-x} dx = 1 - e^{-a}$$

Example:

The joint density of X & Y is given by,

$$f(x, y) = \begin{cases} e^{-(x+y)} & 0 < x < \infty, 0 < y < \infty \\ 0 & \text{otherwise} \end{cases}$$

Find the density func. of the r.v. X/Y .

Soln.

$$F_{X/Y}(a) = P\left\{\frac{X}{Y} \leq a\right\}$$

$$= \iint e^{-(x+y)} dx dy$$

$$(x, y): x/y \leq a$$

$$= \int_0^{\infty} \int_0^{ay} e^{-(x+y)} dx dy$$

$$= \int_0^{\infty} (1 - e^{-ay}) e^{-y} dy$$

$$= \left\{ -e^{-y} + \frac{e^{-(a+1)y}}{a+1} \right\} \Big|_0^{\infty}$$

$$= 1 - \frac{1}{a+1} \rightarrow \textcircled{1}$$

Now, to calculate the density func. of X/Y
we differentiate $\textcircled{1}$, which gives, $f_{X/Y}(a) = \frac{1}{(a+1)^2}$
 $0 < a < \infty$.

Conditional distributions (Discrete case):

For any two events E & F , the ~~prob.~~ conditional prob. of E given F is defined as:

$$P(E|F) = \frac{P(EF)}{P(F)}$$

Thus if X & Y are discrete random variables, the conditional prob. mass func. of X given that $Y=y$, by

$$p_{X|Y}(x|y) = P(X=x | Y=y)$$

$$= \frac{P(X=x, Y=y)}{P(Y=y)}$$

$$= \frac{p_{XY}(x, y)}{p_Y(y)}$$

For all values of y such that $p_Y(y) > 0$. Similarly the conditional prob. distr. func. of X given that $Y=y$ is defined, for all y such that $p_Y(y) > 0$, by

$$F_{X|Y}(x|y) = P\{X \leq x | Y=y\}$$

$$= \sum_{a \leq x} p_{X|Y}(a|y)$$

If X & Y are independent,

$$p_{X|Y}(x|y) = P\{X=x | Y=y\}$$

$$= \frac{P\{X=x, Y=y\}}{P\{Y=y\}}$$

$$= \frac{P\{X=x\} \cdot P\{Y=y\}}{P\{Y=y\}}$$

$$= P\{X=x\}$$

Example

Suppose that $p(x, y)$, the joint probability mass func. of X & Y is given by

$$p(0,0)=0.4, \quad p(0,1)=0.2, \quad p(1,0)=0.1, \quad p(1,1)=0.3$$

calculate the conditional prob. mass func. of X given that $Y=1$.

$$\Rightarrow p_Y(1) = \sum_x p(x,1) = p(0,1) + p(1,1) \\ = 0.5$$

$$\text{Hence, } p_{X|Y}(0|1) = \frac{p(0,1)}{p_Y(1)} = \frac{2}{5}$$

$$\text{and } p_{X|Y}(1|1) = \frac{p(1,1)}{p_Y(1)} = \frac{3}{5}$$

Continuous case:

If X & Y have a joint prob. density func. $f(x, y)$, then the conditional probability density func. of X given that $Y=y$ is defined for all values of y such that $f_Y(y) > 0$ by

$$f_{X|Y}(x|y) = \frac{f(x, y)}{f_Y(y)}$$

~~To motivate~~ If X & Y are jointly cont., then for any set A ,
$$P\{X \in A | Y=y\} = \int_A f_{X|Y}(x|y) dx$$

Example:

(1) The joint density of X & Y is given by

$$f(x, y) = \begin{cases} \frac{12}{5} x(2-x-y) & 0 < x < 1, \\ & 0 < y < 1 \\ 0 & \text{otherwise} \end{cases}$$

Compute the conditional density of X given that $Y=y$,
where $0 < y < 1$.

\Rightarrow For $0 < x < 1$, $0 < y < 1$ we have

$$f_{X|Y}(x|y) = \frac{f_{X,Y}(x,y)}{f_Y(y)}$$

$$= \frac{f_{X,Y}(x,y)}{\int_{-\infty}^{\infty} f_{X,Y}(x,y) dx}$$

$$= \frac{x(2-x-y)}{\int_0^1 x(2-x-y) dx}$$

$$= \frac{x(2-x-y)}{\frac{2}{3} - \frac{y}{2}} = \frac{6x(2-x-y)}{4-3y}$$

② Suppose that the joint density of X & Y are given by,

$$f_{X,Y} = \begin{cases} \frac{e^{-x/y} \cdot e^{-y}}{y} & 0 < x < \infty, 0 < y < \infty \\ 0 & \text{otherwise} \end{cases}$$

Find $P\{X > 1 | Y = y\}$

$$\Rightarrow f_{X|Y}(x|y) = \frac{f_{X,Y}(x,y)}{f_Y(y)}$$

$$= \frac{e^{-x/y} \cdot e^{-y}/y}{e^{-y} \int_0^{\infty} \frac{1}{y} e^{-x/y} dx} = \frac{1}{y} e^{-x/y}$$

Hence, $P\{X > 1 | Y = y\} = \int_1^{\infty} \frac{1}{y} e^{-x/y} dx$

$$= -e^{-x/y} \Big|_1^{\infty}$$

$$= e^{-1/y}$$

Uniform random variable

A random variable is said to be uniformly distributed over the interval $(0,1)$ if its prob. density func. is given by:

$$f(x) = \begin{cases} 1 & 0 < x < 1 \\ 0 & \text{otherwise} \end{cases} \rightarrow (1)$$

$$\text{Since } f(x) \geq 0 \text{ and } \int_{-\infty}^{\infty} f(x) dx = \int_0^1 dx = 1.$$

For any $0 < a < b < 1$,

$$P(a \leq x \leq b) = \int_a^b f(x) dx = b - a.$$

In general, we say that X is a uniform random variable on the interval (α, β) if the probability density func. of X is given by:

$$f(x) = \begin{cases} \frac{1}{\beta - \alpha} & \text{if } \alpha < x < \beta \\ 0 & \text{otherwise} \end{cases} \rightarrow (2)$$

Since $F(x) = \int_{-\infty}^x f(x) dx$, it follows from (2) that the distribution func. of a uniform random variable on the interval (α, β) is given by:

$$F(x) = \begin{cases} 0 & x \leq \alpha \\ \frac{x - \alpha}{\beta - \alpha} & \alpha < x < \beta \\ 1 & x \geq \beta \end{cases}$$

Example:

Let X be uniformly distributed over (α, β) .

(i) Find $E(X)$

(ii) Find $\text{Var}(X)$.

$$\begin{aligned}
 \Rightarrow (i) E(X) &= \int_{-\infty}^{\infty} x f(x) dx \\
 &= \int_{\alpha}^{\beta} \frac{1}{\beta - \alpha} x dx \\
 &= \frac{\beta^2 - \alpha^2}{2(\beta - \alpha)} = \frac{(\beta + \alpha)}{2}
 \end{aligned}$$

$$\begin{aligned}
 (ii) E(X^2) &= \int_{\alpha}^{\beta} \frac{1}{\beta - \alpha} x^2 dx \\
 &= \frac{\beta^3 - \alpha^3}{3(\beta - \alpha)} = \frac{\beta^2 + \alpha\beta + \alpha^2}{3}
 \end{aligned}$$

$$\begin{aligned}
 \text{hence, } \text{Var}(X) &= E(X^2) - [E(X)]^2 \\
 &= \frac{(\beta - \alpha)^2}{12}
 \end{aligned}$$

(2) If X is uniformly distr. over $(0, 10)$, calculate the prob

$$(i) X < 3 \Rightarrow P\{X < 3\} = \int_0^3 \frac{1}{10} dx = \frac{3}{10}$$

$$(ii) X > 6 \Rightarrow P\{X > 6\} = \int_6^{10} \frac{1}{10} dx = \frac{4}{10}$$

$$(iii) 3 < X < 8 \Rightarrow P\{3 < X < 8\} = \int_3^8 \frac{1}{10} dx = \frac{1}{2}$$
